RETROVIRAL PROTEASE INHIBITING COMPOUNDS

This is a continuation-in-part of U.S. Patent application Serial No. 456,124, filed December 22, 1989, which is a continuation-in-part of U.S. Patent application Serial No. 405,604, filed September 8, 1989, which is a continuation-in-part of U.S. Patent application Serial No. 355,945, filed May 23, 1989.

Technical Field

This invention was made with Government support under contract number AI27220-01 awarded by the National Institute of Allergy and Infectious Diseases. The Government has certain rights in this invention.

The present invention relates to novel compounds and a composition and method for inhibiting retroviral proteases and in particular for inhibiting human immunodeficiency virus (HIV) protease, a composition and method for treating a retroviral infection and in particular an HIV infection, processes for making such compounds and synthetic intermediates employed in these processes.

Background Art

Retroviruses are those viruses which utilize a ribonucleic acid (RNA) intermediate and a RNA-dependent deoxyribonucleic acid (DNA) polymerase, reverse transcriptase, during their life cycle. Retroviruses include, but are not limited to, the RNA viruses of the Retroviridae family, and also the DNA viruses of the Hepadnavirus and Caulimovirus families. Retroviruses cause a variety of disease states in man, animals and plants. Some of the more important retroviruses from a pathological standpoint include human immunodeficiency viruses (HIV-1 and HIV-2), which cause acquired immune deficiency syndrome (AIDS) in man, hepatitis B virus, which causes hepatitis and hepatic carcinomas in man, human T-cell lymphotropic viruses I, II, IV and V, which cause human acute cell leukemia, and bovine and feline leukemia viruses which cause leukemia in domestic animals.

Proteases are enzymes which cleave proteins at specific peptide bonds. Many biological functions are controlled or mediated by proteases and their complementary protease inhibitors. For example, the protease renin cleaves the peptide angiotensinogen to produce the peptide angiotensin I. Angiotensin I is further cleaved by the protease angiotensin converting enzyme (ACE) to form the hypotensive peptide angiotensin II. Inhibitors of renin and ACE are known to reduce high blood pressure *in vivo*. An inhibitor of a retroviral protease should provide a therapeutic agent for diseases caused by the retrovirus.

The genomes of retroviruses encode a protease that is responsible for the proteolytic processing of one or more polyprotein precursors such as the *pol* and *gag* gene products. See Wetlink, Arch. Virol. 98 1 (1988). Retroviral proteases most commonly process the *gag* precursor into core proteins, and also process the *pol* precursor into reverse transcriptase and retroviral protease. In addition, retroviral proteases are sequence specific. See Pearl, Nature 328 482 (1987).

The correct processing of the precursor polyproteins by the retroviral protease is necessary for the assembly of infectious virions. It has been shown that *in vitro* mutagenesis that produces protease-defective virus leads to the production of immature core forms which lack infectivity. See Crawford, J. Virol. 53 899 (1985); Kato, et al., Virology 145 280 (1985). Therefore, retroviral protease inhibition provides an attractive target for antiviral therapy. See Mitsuya, Nature 325 775 (1987).

Current treatments for viral diseases usually involve administration of compounds that inhibit viral DNA synthesis. Current treatments for AIDS (Dagan, Chem. Eng. News, November 23, 1987 pp. 41-49) involve administration of compounds such as 2,3-dideoxycytidine, trisodium phosphonoformate, ammonium 21-tungsto-9-antimonate, 1-beta-D-ribofuranosyl-1,2,4-triazole-3-carboxamide, 3-azido-3-deoxythymidine, and adriamycin that inhibit viral DNA synthesis; compounds such as AL-721 and polymannoacetate which may prevent HIV from penetrating the host cell; and compounds which treat the opportunistic infections caused by the immunosuppression resulting from HIV infection. None of the current AIDS treatments have proven to be totally effective in treating and/or reversing the disease. In addition, many of the compounds currently used to treat AIDS cause adverse side effects including low platelet count, renal toxicity and bone marrow cytopenia.

Heterocyclics also include:

Heterocyclics can be unsubstituted or monosubstituted or disubstituted with substituents independently selected from hydroxy, halo, oxo ($=\text{O}$), alkylimino ($\text{R}^*\text{N}=\text{}$ wherein R^* is a loweralkyl group), amino, alkylamino, dialkylamino, alkoxy, polyalkoxy, haloalkyl, cycloalkyl, $-\text{COOH}$, $-\text{SO}_3\text{H}$ and loweralkyl. In addition, nitrogen containing heterocycles can be N-protected.

The term "(heterocyclic)alkyl" as used herein refers to a heterocyclic group appended to a loweralkyl radical, including but not limited to imidazolylmethyl, thiazolylmethyl, pyridylmethyl and morpholinylmethyl.

The term "heterocyclic carbonyloxy" as used herein refers to $R_{304}C(O)O-$ wherein R_{304} is a heterocyclic group.

The term "heterocyclic carbonylamino" as used herein refers to $R_{305}C(O)NH-$ wherein R_{305} is a heterocyclic group.

In the compounds of the present invention, the A, X and B components may have asymmetric centers and occur as racemates, racemic mixtures, mixtures of diastereomers and as individual diastereomers, with all isomeric forms being included in the invention.

When any variable (i.e., R_1 , R_2 , R_3 , etc.) occurs more than one time in any constituent or in a compound of Formula I, its definition on each occurrence is independent of its definition at every other occurrence. Also, combinations of substituents and/or variables are permissible only if such combinations result in stable compounds.

Representative compounds of the invention include those represented in Table 2. (In the table "Ph" represents phenyl and p-C₇H₇ represents 4-methylphenyl).

The compounds of the invention can be prepared as shown in Schemes 1-13. The syntheses of segments (II), (III), (IV), and (V) are described in the Examples. The process shown in Scheme 1 discloses the condensation of carboxylic or sulfonic acid $G-OH$ to segments (II) and (III) in the presence of a coupling reagent to give (VI) and (VII), respectively. The process shown in Scheme 1 also discloses the condensation of segments (IV) and (V) to NR_3R_4 in the presence of a coupling reagent to give (VIII) and (IX), respectively. Coupling reagents known in the art which can be used include, but are not limited to, dicyclohexylcarbodiimide (DCC), 3-ethyl-3'-(dimethylamino)propylcarbodiimide (EDC), bis(2-oxo-3-oxazolidinyl)-phosphinic chloride (BOP-Cl), diphenylphosphoryl azide (DPPA) and the like.

In addition to the use of the carboxylic acids or sulfonic acids shown in the scheme, acid halide and other activated ester derivatives of the carboxylic acid or sulfonic acid are useful for the coupling reactions with (II), (III), and HNR_3R_4 . Acid halide derivatives include the acid chloride. Activated ester derivatives include activated esters commonly used by those skilled in the art for activating carboxylic acid groups for coupling with an amine to form an amide bond or for coupling with an alcohol to form an ester bond including, but not limited to, formic and acetic acid derived anhydrides, anhydrides derived from alkoxycarbonyl halides such as isobutyloxycarbonylchloride and the like, N-hydroxysuccinimide derived esters, N-hydroxyphthalimide derived esters, N-hydroxybenzotriazole derived esters, N-hydroxy-5-norbornene-2,3-dicarboxamide derived esters, 2,4,5-trichlorophenol derived esters and the like.

The compounds of the invention having a fluorinated X group can be prepared as shown in the synthetic Scheme 2. The process shown in the synthetic scheme shows the preparation of the key intermediate XV. The synthesis starts with a protected amino alcohol X, which was oxidized by Swern oxidation to the corresponding aldehyde XI. Reformatsky reaction with ethyl bromodifluoroacetate provided XII. Deprotection of XII, followed by treatment with phosgene gave XIII which upon hydrolysis of the ester and treatment with an organometallic such as an alkyl lithium or alkyl Grignard provided compound XIV. Oxime formation from XIV and hydrogenation, followed by basic hydrolysis of the oxazolidinone ring gave the key intermediate XV. Coupling of protected amino acid, or amino acid derivatives or peptidyl fragments J to the intermediate XV provides the compounds of the invention XVI. Oxidation of XVI provided the compounds of the invention XVII.

Compounds of the invention wherein X is $-CH(OR_{11})-$ can be prepared as shown in Scheme 3. The process shown in Scheme 3 discloses the reduction and subsequent addition of vinylmagnesium bromide to protected aminocarbonate XVIII. The resulting allylic alcohol XIX is mesylated to provide XX, which is treated with a Grignard reagent and catalytic $CuCN$ to provide olefin XXI. Epoxidation of XXI leads to XXII which is regioselectively opened with azide anion to provide XXIII. Reduction of the azide gives XXIV and deprotection provides XXV, both of which can be coupled according to Scheme 1 to provide compounds of the invention.

Compounds of the invention wherein X is $-CH(OR_{11})-CH(OR_{12})-$ can be prepared as shown in Scheme 4. The process shown in Scheme 4 discloses the oxidation of XXVI to protected aminoaldehyde XXVII. Reductive dimerization of XXVII provides the doubly protected diaminodiol XXVIII, which is deprotected to give diaminodiol XXIX. Coupling of XXIX according to Scheme 1 provides compounds of the invention.

Compounds of the invention of the type XXXII, in which $d=0$ or 1 and R_3 and R_{12} are as defined above, may be prepared as outlined in Scheme 5. Thus the known aziridine XXX (Y. L. Merrer, et al *Heterocycles*, 1987, 25, 541-548) is acylated (e.g. with $G=Cbz$ -valine), sulfonated (e.g. with $G=p$ -toluene sulfonic acid), or phosphorylated (e.g. with G =diphenylphosphinic acid), to provide compounds of the formula XXXI. These compounds are in turn treated with various nucleophiles, such as thiols, alcohols, amines, or organometallic reagents, which serve to open the aziridine ring. The acetamide can be removed by acid hydrolysis. When G is a sulfonic acid residue, e.g. p -toluenesulfonyl, this group may be removed reductively, for example, with sodium in liquid ammonia or with sodium naphthalenide, to provide compounds of the formula XXXII wherein G is hydrogen. These compounds, in turn, can be N-acylated with protected amino acids, e.g. Cbz-valine, to provide additional compounds of the formula XXXII.

As outlined in Scheme 6, compounds of the invention of the formula XXXVI and XXXVII may be prepared by acylation of XXXIII with bromoacetyl bromide, followed by displacement of the bromide with various amine nucleophiles. R_{12} and R_{13} may be selected independently from hydrogen and alkyl, or may constitute a heterocyclic ring incorporating the nitrogen to which they are appended, e.g., rings such as morpholine, piperidine, and piperazine. Compounds of the invention of formula XL and XLI may be prepared by acylation of XXXIII with (chloromethyl)benzoyl chloride, followed by displacement of the benzylic chloride group with various amine nucleophiles.

As outlined in Scheme 7, compounds of the invention of formula XLV and XLVI, and L and LI, are prepared in analogous fashion from compounds XLII and XLVII.

As outlined in Scheme 8, compounds of the invention of the formula LIII are prepared from compounds of the formula LII by treatment with diazomethane. Compounds of the formula LIV may be oxidized to ketones of the formula LV by treatment with the oxalyl chloride/DMSO reagent followed by treatment with triethylamine. Ketones of the formula LV may be converted to epoxides of the formula LVI by treatment with diazomethane.

As outlined in Scheme 9, the compound of the formula LVII (C. H. Chen, et al, *J. Org. Chem.*, 1981, 46, 2752-2757) is converted to the compound of the formula LVIII by hydrogenation, reduction with sodium borohydride, followed by saponification of the ester to provide the diacid. This compound is in turn, coupled with various amino acid esters or amides to provide compounds of the formula LIX, wherein R_{SO_2} may be NH or O, and R_3 is as defined above.

As outlined in Scheme 10, compounds of the formula LX (W.N. Haworth, et al, *J. Chem. Soc.*, 1944, 217) are treated with amino acid esters or amides, followed by acetone with an acid catalyst, followed by triflic anhydride to provide compounds of the formula LXI, wherein R_{SO_2} may be NH or O, and R_3 is as defined above. These compounds are in turn treated with various alcohol, thiol, or amine nucleophiles, followed by acid catalyzed hydrolysis of the acetonide, to provide compounds of the formula LXII, wherein R_{SO_2} may be NH or O, and R_3 and R_{SO_2} are as defined above.

As outlined in Scheme 11, the diepoxide LXIII (R.S. Tipson, et al, *Carbohydrate Research*, 1968, 7, 232-243) is converted to the diester of the formula LXIV by oxidation, first with the DMSO/oxalyl chloride/triethylamine reagent (Swern reagent) to the dialdehyde, and then with bromine in methanol:aqueous sodium bicarbonate. This compound is in turn treated with various alcohol, thiol, or amine nucleophiles, or with organometallic nucleophiles, followed by protection of the alcohols with a protecting group P' , to provide compounds of the formula LXV, wherein $d = 0$ or 1 , and R_{SO_2} and R_3 are as defined above. Saponification of LXV followed by coupling with various amino acid esters or amides and deprotection of the alcohol protecting groups provides compounds of the formula LXVI, wherein R_{SO_2} may be NH or O, $d = 0$ or 1 , and R_{SO_2} and R_3 are as defined above.

As outlined in Scheme 12, the compound of the formula LXIII may be oxidized with the Swern reagent in a solvent like THF, and without isolation, treated with an organometallic reagent, such as a Grignard reagent, to provide compounds of the formula LXVII. These compounds, may in turn, be converted to the carbamates LXVIII with an isocyanate, wherein R_{SO_2} is hydrogen or benzyl or substituted benzyl. These carbamates may then be treated with a strong base such as potassium *t*-butoxide or sodium hydride in a suitable solvent such as THF, and the resulting cyclic carbamates treated with hydrogen over a palladium catalyst to provide compounds of the formula LXIX.

As outlined in Scheme 13, compounds of the formula LV may be converted to the oxime LXX with hydroxylamine hydrochloride in the presence of pyridine. These compounds may then be reduced with hydrogen over a catalyst to provide compounds of the formula LXXI.

Example 10A 2-(t-Butyloxycarbonylamino)-1,5-diphenylpent-3-ene.

A solution of 15.1 g (54.5 mmol) of the resultant compound of Example 6A and 38 ml (220 mmol) of diisopropylethylamine in 450 ml of dry dichloromethane was cooled under N₂ atmosphere in an acetone ice bath and treated dropwise with 8.5 ml (110 mmol) of methanesulfonyl chloride. The solution was stirred for 7 min after addition was complete, then was quenched with 400 ml of 10% citric acid. The bath was removed, and the mixture was extracted with 800 ml of ether. The organic layer was washed sequentially with 500 ml of water and 300 ml of saturated brine, dried over MgSO₄, and concentrated in vacuo to give the crude mesylate as an off-white solid. To a flame-dried 3-neck 1000 mL flask equipped with an internal low-temperature thermometer was added 1.45 g (16 mmol) of anhydrous cuprous cyanide. The flask was then charged with 500 ml of anhydrous tetrahydrofuran. The suspension was cooled under N₂ atmosphere in a dry ice/acetone bath. A solution of phenylmagnesium bromide (55 ml, 165 mmol) in ether (3M) was added via syringe. The bath was removed, and the resulting beige suspension was warmed with stirring by use of a water bath. As the internal temperature reached -5 °C, the solid began to dissolve, and the solution began to turn darker. By the time the internal temperature reached -1 °C, the solution was homogenous, and was immediately recooled by placement of the flask in a dry ice/acetone bath. As the internal temperature reached -65 °C, addition of a solution of the above crude mesylate in 75 ml of tetrahydrofuran was added via cannula. The resulting solution was stirred at ca. -70 °C for 15 min. The bath was then removed, and the solution was immediately treated with 100 ml of saturated aqueous ammonium chloride followed by 300 ml of ether. As the mixture warmed, 100 ml of 1 N NH₄OH was added, and the mixture was stirred under air atmosphere for several hours while the aqueous layer turned dark blue. The mixture was then extracted with 500 ml of ether. The organic layer was washed with saturated brine and concentrated in vacuo without drying to give a yellow oil. The combined aqueous layers were extracted with 500 ml of additional ether, which was added to the above oil. The resulting solution was washed with saturated brine, dried over MgSO₄, and concentrated to a yellow oil. The oil was taken up in 100 ml of dichloromethane, treated with 50 g of silica gel, and concentrated in vacuo until the residue was a freely flowing solid. The solid was placed on top of a 60 mm column containing 300 g of silica gel and eluted sequentially with 1200 ml of hexane (to bring out biphenyl formed as a side product) followed by 5000 ml of 5% ethyl acetate in hexane. Combination of the pure fractions gave 11.95 g (65%) of the desired compound. ¹H NMR (CDCl₃, major isomer) δ 1.40 (s, 9 H), 2.7-2.9 m, 2 H), 3.32 (d, J = 7 Hz, 2 H), 4.4 (br, 2 H), 5.43 (dd, J = 15, 6 Hz, 1 H) 5.64 (dt, J = 15, 7 Hz, 1 H), 7.0-7.3 (m, 10 H).

The resulting suspension was sealed with a septum and stirred in a cold room (5 °C) for three days. The resulting mixture, which contained much precipitate, was decanted into a 1000 ml flask. The white residue was broken up and washed out with 400 ml of 10% sodium thiosulfate solution and 300 ml of ether. The two-phase mixture was stirred for 2 hours, and the layers were separated. The organic layer was washed sequentially with 200 ml portions of 2 M NaOH, water, and saturated brine. The combined aqueous layers were extracted with 200 ml of ether, which was washed sequentially with 50 ml of water and 50 mL of aqueous brine, combined with the original organic phase, dried over MgSO₄, and concentrated in vacuo. The resulting oil was taken up in 100 ml of dichloromethane, treated with 50 g of silica gel, and concentrated in vacuo until the residue was a freely flowing solid. The solid was placed on top of a 60 mm column containing 300 g of silica gel and eluted sequentially with 1000 ml of 5% ethyl acetate in hexane followed by 3500 ml of 12% ethyl acetate in hexane. Tipson, et al. *Carbohydrate Research*, 1968, 7, 232-243) as described in Example 306, but substituting THF for the dichloromethane DMSO mixture as solvent, affords a solution of the corresponding dialdehyde. This solution is then recooled to -78°C , and treated with four equivalents (relative to the iditol) of phenylmagnesium bromide. The reaction mixture is then quenched with a pH 7 phosphate buffer and extracted into ethyl acetate, dried over sodium sulfate, and concentrated under reduced pressure. The resulting diol is treated with benzyl isocyanate, in the presence of either DMAP or diisopropylethylamine, in an inert solvent, such as benzene or THF. The resulting biscarbamate is then treated with 2 equivalents of NaH or potassium *t*-butoxide in THF. The resulting diol is then treated with hydrogen over a Pd catalyst in a solvent such as MeOH to afford (2S, 3S, 4S, 5S)-3,4-dihydroxy-1,6-diphenyl-hexane-2,5-diamine. This is then converted into the title compound by treatment with Cbz-valine *p*-nitrophenyl ester in THF in the presence of triethylamine.

Fluorogenic Assay for Screening Inhibitors of HIV Protease

The inhibitory potency of the compounds of the invention can be determined by the following method.

- 25 A compound of the invention is dissolved in DMSO and a small aliquot further diluted with DMSO to 100 times the final concentration desired for testing. The reaction is carried out in a 6 X 50 mm tube in a total volume of 300 microliters. The final concentrations of the components in the reaction buffer are: 125 mM sodium acetate, 1 M sodium chloride, 5 mM dithiothreitol, 0.5 mg/ml bovine serum albumin, 1.3 uM fluorogenic substrate, 2% (v/v) dimethylsulfoxide, pH 4.5. After addition of inhibitor, the reaction mixture is placed in the fluorometer cell holder and incubated at 30 °C for several minutes. The reaction is initiated by the addition of a small aliquot of cold HIV protease. The fluorescence intensity (excitation 340 nM, emission 490 nM) is recorded as a function of time. The reaction rate is determined for the first six to eight minutes. The observed rate is directly proportional to the moles of substrate cleaved per unit time. The percent inhibition is $100 \times (1 - (\text{rate in presence of inhibitor})/(\text{rate in absence of inhibitor}))$.

- 35 Fluorogenic substrate: Dabcyl-Ser-Gln-Asp-Tyr-Pro-Ile-Val-Gln-EDANS wherein DABCYL = 4-(4-dimethylaminophenyl)azobenzoic acid and EDANS = 5-((2-aminoethyl)amino)naphthalene-1-sulfonic acid.

Compounds of the invention inhibit HIV-1 protease at concentrations between 0.01 nM and 500,000 nM. Table 3 shows the inhibitory potencies of specific compounds of the invention against HIV-1 protease.

Antiviral Activity

The anti-HIV activity of the compounds of the invention can be determined by the following method.

A mixture of 0.1 ml (2×10^5 cells/ml) of H9 cells and 0.1 ml (100 infectious units) of HIV-1₃₈ was incubated on a shaker for 2 h at 37°C. The resulting culture was washed three times and resuspended into 2 ml of medium containing 10 μ l of a compound of the invention in dimethylsulfoxide. The control culture was treated in an identical manner except no compound was added to the medium. Aliquots of culture supernatants were removed at 3 time points, usually 4, 7 and 10 days, and monitored for HIV-1 antigen EIA (HIVAG-1) (Paul, et al., J. Med. Virol., 22 357 (1987)). Cell viability was determined by trypan blue dye exclusion, and cells were refed with media containing compound (except for control wells which were refed with media only) at these time points. Per cent inhibition of HIV by the compound was determined by comparing HIV antigen levels in the supernatants of infected cells incubated with compound to supernatants from the control culture without compound. The IC_{50} is the concentration of compound that gives 50% inhibition of HIV activity. The LD_{50} is the concentration of compound at which 50% of the cells remain viable.

Table 4 shows the inhibitory potencies of compounds of the invention against HIV-1 in H9 cells:

Additionally a decrease in infectivity of HIV as a measure of anti-HIV activity of the compounds of the invention can be assessed as follows:

After incubation of the culture containing a compound of the invention as described above for approximately 6 days (range: 4-10 days), an aliquot (0.1 ml) of the supernatant was withdrawn. 5-fold dilutions were made in media, and these dilutions were then incubated with fresh H9 cells (4×10^5 cells/ml) on a shaker for 2 hr at 37°C . The resulting cultures were washed three times, resuspended in 2 ml of medium with and without compound, and incubated and maintained as above. Production of virus in the culture supernatant was monitored at various time points using the Abbott HIV-1 antigen EIA. Loss of infectivity was determined by comparing HIV antigen end point dilutions of cultures with and without compound. In this manner, the compound of Example 70 reduced the HIV infectivity 25-fold.

The amino acid esters of particular interest are glycine and lysine; however, other amino acid residues can also be used, including those wherein the amino acyl group is $-\text{C}(\text{O})\text{CH}_2\text{NR}_{100}\text{R}_{101}$, wherein R_{100} and R_{101} are independently selected from hydrogen and loweralkyl or the group $-\text{NR}_{100}\text{R}_{101}$ forms a nitrogen containing heterocyclic ring. These esters serve as pro-drugs of the compounds of the present invention and serve to increase the solubility of these substances in the gastrointestinal tract. These esters also serve to increase solubility for intravenous administration of the compounds. These pro-drugs are metabolized *in vivo* to provide the hydroxyl-substituted compound of formula I. The preparation of the pro-drug esters is carried out by reacting a hydroxyl-substituted compound of formula I with an activated amino acyl, phosphoryl, hemisuccinyl or substituted benzoyl derivative as defined above. The resulting product is then deprotected to provide the desired pro-drug ester.

The compounds of the present invention are useful for the treatment or prophylaxis of diseases caused

by retroviruses in mammals (especially humans) and are particularly useful for the treatment or prophylaxis of acquired immune deficiency syndrome or an HIV infection.

Total daily dose administered to a host in single or divided doses may be in amounts, for example, from 0.001 to 10 mg/kg body weight daily and more usually 0.01 to 1 mg. Dosage unit compositions may contain such amounts of submultiples thereof to make up the daily dose.

The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration.

It will be understood, however, that the specific dose level for any particular patient will depend upon a variety of factors including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, route of administration, rate of excretion, drug combination, and the severity of the particular disease undergoing therapy.

The compounds of the present invention may be administered orally, parenterally, by inhalation spray, by aerosols, rectally, or topically in dosage unit formulations containing conventional nontoxic pharmaceutically acceptable carriers, adjuvants, and vehicles as desired. Topical administration may also involve the use of sublingual dosage forms, transdermal administration such as transdermal patches or iontophoresis devices. The term parenteral as used herein includes subcutaneous injections, intravenous, intramuscular, intrasternal injection, or infusion techniques.

Injectable preparations, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a nontoxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable nonirritating excipient such as cocoa butter and polyethylene glycols which are solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum and release the drug.

Solid dosage forms for oral administration may include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound may be admixed with at least one inert diluent such as sucrose, lactose, or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than inert diluents, e.g., lubricating agents such as magnesium stearate. In the case of capsules, tablets, and pills, the dosage forms may also comprise buffering agents. Tablets and pills can additionally be prepared with enteric coatings.

Liquid dosage forms for oral administration may include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs containing inert diluents commonly used in the art, such as water. Such compositions may also comprise adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring, and perfuming agents.

The present agents can also be administered in the form of liposomes. As is known in the art, liposomes are generally derived from phospholipids or other lipid substances. Liposomes are formed by mono- or multi-lamellar hydrated liquid crystals that are dispersed in an aqueous medium. Any non-toxic, physiologically acceptable and metabolizable lipid capable of forming liposomes can be used. The present compositions in liposome form can contain, in addition to a compound of the present invention, stabilizers, preservatives, excipients, and the like. The preferred lipids are the phospholipids and the phosphatidylcholines (lecithins), both natural and synthetic.

Methods to form liposomes are known in the art. See, for example, Prescott, Ed., Methods in Cell Biology, Volume XIV, Academic Press, New York, N. Y. (1976), p. 33 et seq.

While the compounds of the invention can be administered as the sole active pharmaceutical agent, they can also be used in combination with one or more immunomodulators, antiviral agents, other anti-infective agents or vaccines. Other antiviral agents to be administered in combination with a compound of the present invention include AL-721, beta interferon, polymannosacetate, ganciclovir, dideoxycytidine, trisodium phosphonoformate, HPA-23, efloornithine, Peptide T, Reticulose (nucleophosphoprotein), zidovudine (AZT), ansamycin LM 427, trimetrexate, UA001, ribavirin, alpha interferon and acyclovir. Immunomodulators that can be administered in combination with a compound of the present invention include brosimine, Ampligen, anti-human alpha interferon antibody, colony stimulating factor, CL246 738, Imreg-1, Imreg-2, diethyldithiocarbamate, interleukin-2, alpha-interferon, inosine pranobex, methionine enkephalin, muramyl-tripeptide, TP-5, erythropoietin, naltrexone and tumor necrosis factor. Other anti-infective agents that can be administered in combination with a compound of the present invention include

pentamidine isethionate. Any of a variety of HIV or AIDS vaccines can be used in combination with a compound of the present invention.

It will be understood that agents which can be combined with the compounds of the present invention for the treatment or prophylaxis of AIDS or an HIV infection are not limited to those listed above, but include in principle any agents useful for the treatment or prophylaxis of AIDS or an HIV infection.

When administered as a combination, the therapeutic agents can be formulated as separate compositions which are given at the same time or different times, or the therapeutic agents can be given as a single composition.

The foregoing is merely illustrative of the invention and is not intended to limit the invention to the disclosed compounds. Variations and changes which are obvious to one skilled in the art are intended to be within the scope and nature of the invention which are defined in the appended claims.
